

Wrap-up; Terms and definitions from Course 5, Week 2

Our focus in this section was on a major theme of security: protecting assets.

A large part of this relates to privacy.

We should all enjoy the right to decide who can access our information.

As we learned, there are several controls in place that help secure assets.

We began the section by exploring effective data handling processes that are founded on the principle of least privilege.

We then explored the role of encryption and hashing and safeguarding information.

We explored how symmetric and asymmetric encryption works and how hashes further safeguard data from harm.

We then turned our attention to standard access controls. Properly authenticating and authorizing users is what maintaining the CIA triad of information is all about!

We used the AAA framework of security to take a detailed tour of identity and access management systems and the access controls that validate whether or not someone is who they claim to be.

Well done making it through the first half of the course!

You're making great progress so far, and I hope you keep it up.

Remember, your background and experiences are valuable in this field.

This combined with the concepts we're covering will make you a valuable contributor to any security team.

Up until this point, we've been exploring the defensive side of security, but security isn't all about planning ahead and waiting for something to happen.

In the next part of our journey,

we're going to continue developing a security mindset by taking a more proactive look at security from the perspective of attackers.

I'll meet you there!

Glossary terms from week 2

Access controls: Security controls that manage access, authorization, and accountability of information

Algorithm: A set of rules used to solve a problem

Application programming interface (API) token: A small block of encrypted code that contains information about a user

Asymmetric encryption: The use of a public and private key pair for encryption and decryption of data

Basic auth: The technology used to establish a user's request to access a server

Bit: The smallest unit of data measurement on a computer

Brute force attack: The trial and error process of discovering private information

Cipher: An algorithm that encrypts information

Cryptographic key: A mechanism that decrypts ciphertext

Cryptography: The process of transforming information into a form that unintended readers can't understand

Data custodian: Anyone or anything that's responsible for the safe handling, transport, and storage of information

Data owner: The person that decides who can access, edit, use, or destroy their information

Digital certificate: A file that verifies the identity of a public key holder

Encryption: The process of converting data from a readable format to an encoded format

Hash collision: An instance when different inputs produce the same hash value

Hash function: An algorithm that produces a code that can't be decrypted

Hash table: A data structure that's used to store and reference hash values

Identity and access management (IAM): A collection of processes and technologies that helps organizations manage digital identities in their environment

Information privacy: The protection of unauthorized access and distribution of data

Multi-factor authentication (MFA): A security measure that requires a user to verify their identity in two or more ways to access a system or network

Non-repudiation: The concept that the authenticity of information can't be denied

OAuth: An open-standard authorization protocol that shares designated access between applications

Payment Card Industry Data Security Standards (PCI DSS): A set of security standards formed by major organizations in the financial industry

Personally identifiable information (PII): Any information used to infer an individual's identity

Principle of least privilege: The concept of granting only the minimal access and authorization required to complete a task or function

Protected health information (PHI): Information that relates to the past, present, or future physical or mental health or condition of an individual

Public key infrastructure (PKI): An encryption framework that secures the exchange of online information

Rainbow table: A file of pre-generated hash values and their associated plaintext

Salting: An additional safeguard that's used to strengthen hash functions

Security assessment: A check to determine how resilient current security implementations are against threats

Security audit: A review of an organization's security controls, policies, and procedures against a set of expectations

Security controls: Safeguards designed to reduce specific security risks

Separation of duties: The principle that users should not be given levels of authorization that would allow them to misuse a system

Session: A sequence of network HTTP basic auth requests and responses associated with the same user

Session cookie: A token that websites use to validate a session and determine how long that session should last

Session hijacking: An event when attackers obtain a legitimate user's session ID

Session ID: A unique token that identifies a user and their device while accessing a system

Single Sign-On (SSO): A technology that combines several different logins into one

Symmetric encryption: The use of a single secret key to exchange information

User provisioning: The process of creating and maintaining a user's digital identity
